| Player  | Justin                     | Focus  | Lower-Half Timing / Stability |
| Program | Future Stars Baseball Club | Format | English PDF                   |

## Overall Summary

Justin has a powerful, aggressive swing with very good explosiveness and a solid bat-to-ball foundation. The main issue is not strength. The bigger issue is **lower-half timing and sequencing**: the hips rotate too early, the back knee can drift, and the body moves forward faster than he can control.

| Strengths                                                                                                                                                                                                                                                | Development Priorities                                                                                                                                                                                                                                                  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>Explosive swing intent and strong body speed.</li> <li>Good bat-to-ball foundation.</li> <li>Clear ability to generate force.</li> <li>Power ceiling can improve if lower-half timing becomes cleaner.</li> </ul> | <ul style="list-style-type: none"> <li>Control the back knee during the forward move.</li> <li>Delay hip rotation until the front side is stable.</li> <li>Prevent the front leg from opening early.</li> <li>Improve adjustability against faster pitching.</li> </ul> |

## Key Findings

### Early hip rotation

Justin's hips rotate before the body has fully stabilized. This creates power, but it also makes timing and contact less repeatable.

### Back knee drift

The back knee slightly drifts during the move forward. This creates fast forward movement and can leak energy before the barrel arrives.

### Front side opens early

The front leg begins turning outward before the swing fully launches. This is connected to the early hip rotation and makes the swing harder to control.

### Faster pitching risk

The issue may not look severe in tee work or front toss, but faster pitching will make the timing challenge much more obvious.

| Observation            | Why It Matters                                             |
|------------------------|------------------------------------------------------------|
| Early hip rotation     | Can cause the swing to lose consistency.                   |
| Back knee drift        | Makes forward movement harder to control.                  |
| Front side opening     | Reduces stability and can create a power leak.             |
| Tee/front toss success | May not fully predict performance against faster pitching. |

Training Plan

- **Back-Knee Control Drill:** move forward while keeping the back knee inside and connected; swing only after landing under control.
- **Front-Foot-Down Hold Drill:** pause at landing and check whether the body is stable, the knee is controlled, and the front side has not opened early.
- **Coil-Land-Rotate Drill:** feel the sequence of coil, land, then rotate instead of rotating before the landing position is stable.
- **Middle-Field Timing Drill:** drive balls through the middle so the body does not spin open too early.

| Training Focus       | Success Marker                              |
|----------------------|---------------------------------------------|
| Back knee control    | Knee stays inside during forward move.      |
| Front-side stability | Front leg does not open before launch.      |
| Hip timing           | Rotation happens after landing, not before. |
| Contact consistency  | More line drives through the middle.        |

Vincent's Original Observation

"Justin has a very violent swing displaying very good explosiveness with decently good bat to ball. However, the rotation from the hips occurs too early, causing the swing to lose consistency at times. In addition, Justin's back knee slightly drifts, causing a fast forward movement that is hard to control; this is shown in how his front leg begins to turn outward before the swing even begins. This may not be a big deal while hitting off the tee or front toss, but may become more prominent when timing becomes more difficult with faster pitching. Being able to hold the knee as you make your move forward will provide more stability and consistency with each swing, as well as fixing a power leak that can increase velocity."

Final Coaching Summary

Justin should keep his aggressive swing and explosiveness. The improvement goal is not to make him passive; it is to make his power more controlled. If he can keep the back knee more stable, delay hip rotation, and land before rotating, his swing should become more consistent while preserving power.

Key screenshot from Vincent's original report, used to review the lower-half sequence: back knee control, front-side stability, and early opening.
